 AB - J64003047 Granular inorganic compact contains at least 80% of particles having 0.5-0.9 A/D when D is max. dia., and A is max. length in vertical direction towards the max. dia., and the position of A crossing with D is within + - 0.3 D from the centre of D.
 - The relative density of the compact is, pref., at least 90%, and consists mainly of Ca-phosphate. The inorganic compact is made by compression moulding organic porous body having three dimensional-network in which sinterable inorganic powders are filled to form granular inorganic compact into the pores of the porous body; burning-off the organic porous body and sintering the inorganic compact.
 - USE - For making granular inorganic compact used as a filler for defective portion of bones, or support for immobilised enzyme and catalyst.

 TI - GRANULAR INORGANIC COMPACT AND PRODUCTION THEREOF
 AB - PURPOSE:To readily produce a granular inorganic compact having an uniform shape in high yield, by placing inorganic powder in an organic porous body having a three-dimensional network structure, pressing the organic porous body filled with the inorganic powder, burning up the organic porous body and simultaneously calcining the formed inorganic compacts in pores.
 - CONSTITUTION:Burnable inorganic powder is placed in an organic porous body, such as

polyurethane foam, having a three-dimensional network structure to carry out pressing. Inorganic powders consisting essentially of a calcium phosphate and metallic oxides, such as alumina or zirconia, are cited as the above-mentioned inorganic powder. The aforementioned pressing is preferably carried out under a hydrostatic pressure by an isotropic pressure. Thereby granular inorganic compacts are formed in pores of the above-mentioned porous body. The organic porous body is the burned up to simultaneously calcin the inorganic compacts. The calcining is preferably conducted at ≥ 500 deg.C to provide the aimed granular inorganic compact having 0.5-0.9 ratio (A/D) of the maximum length in the direction perpendicular to the maximum diameter (A) to the diameter (D), $\geq 80\%$ particles having intersections of the (A) and (D) within the range of $\leq 0.3D$ on both sides from the center of the (D) and $\geq 90\%$ relative density is obtained.
